

Labor Induction: Upping Catheter Inflation Helps

VITALS

Major Finding: The likelihood of delivery within 12 hours was significantly increased from 14% with 30-mL Foley catheter inflation to 26% with 60-mL inflation.

Data Source: The prospective LIFT study of 192 women.

Disclosures: Dr. Delaney reported no study sponsorship or conflicts of interest. Coauthor Dr. Aaron Caughey was funded as a Robert Wood Johnson Physician Faculty Scholar.

BY PATRICE WENDLING

CHICAGO — Inflating a transcervical Foley balloon catheter to 60 mL is more effective at inducing labor than standard inflation to 30 mL, based on data from the prospective LIFT study.

The likelihood of delivery within 12 hours was significantly increased from 14% with 30-mL

inflation to 26% with 60-mL inflation. The number needed to treat for this outcome is nine, Dr. Shani Delaney and associates reported at the annual meeting of the Society for Maternal-Fetal Medicine.

“The number needed to treat of nine women provides an achievable intervention without increasing cesarean delivery rates and [while still] maintaining both ma-

ternal and neonatal safety,” she said.

The Labor Induction With a Foley Balloon Trial (LIFT) failed to meet its primary end point of delivery within 24 hours, with 64% of controls and 66% of the 60-mL group achieving this outcome. The percentage of women giving birth within 24 hours was higher than anticipated in both the control and study groups; thus there was not enough statistical power to detect such a small difference between the groups, Dr. Delaney explained in an interview.

As expected, larger balloon inflation to 60 mL produced significantly increased cervical dilation after expulsion compared with 30-mL inflation (4 cm vs. 3 cm).

An 18 French Foley catheter with a 30-mL balloon tip was inflated to 30 mL in 94 evaluable patients and to 60 mL in 98 patients. Intravenous oxytocin was started within 30 minutes of balloon placement.

Only age was significantly higher at 31.4 years in the control group vs. 29.4 years in the 60-mL group.

The study design was influenced by previous trials, which have reported inflation rates of 30-80 mL, Dr. Delaney said.

The American College of Obstetricians and Gynecologists issued a new practice bulletin for labor induction in August 2009 stating that the “Foley catheter is a reasonable and effective alternative for cervical ripening and inducing labor,” but ACOG did not specify inflation sizes.

During the discussion of the study, a member of the audience sounded a word of caution regarding the findings, noting that most manufacturers recommend inflation to only 50 mL.

There was no difference in maternal or neonatal morbidities between treatment groups, said Dr. Delaney of the department of obstetrics and gynecology at the University of Washington in Seattle.

“If only a 30-mL balloon tip is available, inflation to a volume of 60 mL appears to be safe,” she said.

Maternal outcomes that were similar in the control and 60-mL groups included maximum oxytocin dose (19.1 vs. 19.2 mU/min), median delivery time (20 hours vs. 18.8 hours), spontaneous vaginal delivery (66% vs. 63%), cesarean delivery (21% vs. 23%), chorioamnionitis (15% vs. 19%), meconium (21% vs. 20%), cervical laceration (2% vs. 1%), and placental abruption (1% vs. 2%).

Among infants, 5-minute Apgar scores less than 7 were reported in 5% of the 30-mL group and 4% of the 60-mL group. Umbilical artery blood pH was identical in both groups at 7.27, while umbilical artery base excess was -3.38 in the 30-mL group and -2.95 in the 60-mL group.

In a multivariate analysis, delivery within 12 hours was significantly increased with 60-mL balloon inflation among all patients (relative risk, 1.84), and particularly among nulliparous women (RR, 2.88), Dr. Delaney reported. ■

BRIEF SUMMARY

Please see package insert for full Prescribing Information.

INDICATIONS AND USAGE

GELNIQUE is indicated for the treatment of overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency.

GELNIQUE is for topical application only and should not be ingested.

CONTRAINDICATIONS

The use of GELNIQUE is contraindicated in the following conditions:

- Urinary retention
- Gastric retention
- Uncontrolled narrow-angle glaucoma
- Known hypersensitivity to GELNIQUE, including skin hypersensitivity

PRECAUTIONS

Urinary Retention

Administer GELNIQUE with caution in patients with clinically significant bladder outflow obstruction because of the risk of urinary retention.

Patients with Gastrointestinal Disorders

Administer GELNIQUE with caution to patients with gastrointestinal obstructive disorders because of the risk of gastric retention.

GELNIQUE, like other anticholinergic drugs, may decrease gastrointestinal motility and should be used with caution in patients with conditions such as ulcerative colitis or intestinal atony. GELNIQUE should be used with caution in patients who have gastroesophageal reflux and/or who are concurrently taking drugs (such as bisphosphonates) that can cause or exacerbate esophagitis.

Skin Hypersensitivity

In a controlled clinical trial of skin sensitization, 1 of 200 patients (0.5%) demonstrated skin hypersensitivity to GELNIQUE. Patients who develop skin hypersensitivity to GELNIQUE should discontinue drug treatment.

Skin Transference

Transfer of oxybutynin to another person can occur when vigorous skin-to-skin contact is made with the application site. To minimize the potential transfer of oxybutynin from GELNIQUE-treated skin to another person, patients should cover the application site with clothing after the gel has dried if direct skin-to-skin contact at the application site is anticipated. Patients should wash their hands immediately after application of GELNIQUE.

Flammable Gel

GELNIQUE is an alcohol-based gel and is therefore flammable. Avoid open fire or smoking until gel has dried.

Myasthenia Gravis

Administer GELNIQUE with caution in patients with myasthenia gravis, a disease characterized by decreased cholinergic activity at the neuromuscular junction.

ADVERSE REACTIONS

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trial of another drug and may not reflect the rates observed in practice.

The safety of GELNIQUE was evaluated in 789 patients (389 randomized to GELNIQUE 1 g and 400 randomized to placebo) during a randomized, placebo-controlled, double-blind, 12-week clinical efficacy and safety study. A subset of these 789 patients (N=216) participated in the 14-week open-label safety extension that followed the placebo-controlled study. Of 216 patients in the safety extension, 107 were randomized to placebo gel during the double-blind, placebo-controlled 12-week study. In the combined double-blind, placebo-controlled study and the open-label safety extension, a total of 496 patients were exposed to at least one dose of GELNIQUE. Four hundred thirty-one (431) patients received

at least 12 weeks of GELNIQUE treatment and 85 patients received 26 weeks of GELNIQUE treatment. The study population primarily consisted of Caucasian women (approximately 90%) with an average age of 59 years who had overactive bladder with urge urinary incontinence.

Table 1 lists adverse events, regardless of causality, that were reported in the randomized, double-blind, placebo-controlled 12-week study at an incidence greater than placebo and in greater than 2% of patients treated with GELNIQUE.

Table 1: Common Adverse Events in the Randomized, Double-blind, Placebo-controlled 12-Week Study (>2% and > placebo)

Adverse Event	GELNIQUE 1 gram N=389 n (%)	Placebo N=400 n (%)
Dry mouth	29 (7.5)	11 (2.8)
Urinary tract infection	27 (6.9)	17 (4.3)
Application site reactions*	21 (5.4)	4 (1.0)
Upper respiratory tract infection	21 (5.4)	20 (5.0)
Dizziness	11 (2.8)	4 (1.0)
Nasopharyngitis	11 (2.8)	9 (2.3)
Fatigue	8 (2.1)	4 (1.0)
Gastroenteritis viral	8 (2.1)	7 (1.8)

*Includes application site pruritus, dermatitis, papules, anesthesia, erythema, irritation, pain and papules

The most common adverse reactions, defined as adverse events judged by the investigator to be reasonably associated with the use of study drug, that were reported in ≥ 1% of GELNIQUE-treated patients were dry mouth (6.9%), application site reactions (5.4%), dizziness (1.5%), headache (1.5%), constipation (1.3%), and pruritus (1.3%). Application site pruritus (2.1%) and application site dermatitis (1.8%) were the most commonly reported application site reactions. A majority of treatment-related adverse events were described as mild or moderate in intensity, except for two patients reporting severe headache.

No serious adverse events were judged by the investigator to be treatment-related during the randomized, double-blind, placebo-controlled 12-week study. The most common adverse reaction leading to drug discontinuation was application site reaction (0.8% with GELNIQUE versus 0.3% with placebo).

The most common adverse reactions reported during the 14-week open-label extension study were application site reactions (6.0%) and dry mouth (1.9%). The most common reason for premature discontinuation was application site reactions (9 patients or 4.2%). Two of these 9 patients experienced application site reactions of severe intensity (dermatitis, urticaria, and erythema).

DRUG INTERACTIONS

No specific drug-drug interaction studies have been performed with GELNIQUE.

Use With Other Anticholinergics

The concomitant use of GELNIQUE with other anticholinergic (antimuscarinic) agents may increase the frequency and/or severity of dry mouth, constipation, blurred vision, somnolence and other anticholinergic pharmacological effects.

USE IN SPECIFIC POPULATIONS

Pregnancy

Pregnancy Category B

There are no adequate and well-controlled studies of topical or oral oxybutynin use in pregnant women. Subcutaneous administration to rats at doses up to 25 mg/kg (approximately 50 times the human exposure based on surface area) and to rabbits at doses up to 0.4 mg/kg (approximately 1 times the human exposure) revealed no evidence of harm to the fetus due to oxybutynin chloride. The safety of GELNIQUE administration to women who are or who may become pregnant has not been established. Therefore, GELNIQUE should not be given to pregnant women unless, in the judgment of the physician, the probable clinical benefits outweigh the possible hazards.

Nursing Mothers

It is not known whether oxybutynin is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when GELNIQUE is administered to a nursing woman.

Geriatric Use

Of the 496 patients exposed to GELNIQUE in the randomized, double-blind, placebo-controlled 12-week study and the 14-week safety extension study, 188 patients (38%) were 65 years of age and older. No overall differences in safety or effectiveness were observed between these patients and younger patients.

Pediatric Patients

The pharmacokinetics of oxybutynin and N-desethyloxybutynin have not been evaluated in individuals younger than 18 years of age.

Renal Impairment

There is no experience with the use of GELNIQUE in patients with renal impairment.

Hepatic Impairment

There is no experience with the use of GELNIQUE in patients with hepatic impairment.

Race

The effect of race on the pharmacokinetics of GELNIQUE has not been studied.

Gender

Available data suggest that there are no significant differences in the pharmacokinetics of oxybutynin based on gender in healthy volunteers following administration of GELNIQUE.

Use of Sunscreen

The effect of sunscreen on the absorption of oxybutynin when applied 30 minutes before or 30 minutes after GELNIQUE application was evaluated in a single-dose randomized crossover study (N=16). Concomitant application of sunscreen, either before or after GELNIQUE application, had no effect on the systemic exposure of oxybutynin.

Showering

The effect of showering on the absorption of oxybutynin was evaluated in a randomized, steady-state crossover study under conditions of no shower, or showering 1, 2 or 6 hours after GELNIQUE application (N=20). The results of the study indicate that showering after one hour does not affect the overall systemic exposure to oxybutynin.

OVERDOSAGE

Overdosage with oxybutynin has been associated with anticholinergic effects including central nervous system excitation, flushing, fever, dehydration, cardiac arrhythmia, vomiting, and urinary retention. Oral ingestion of 100 mg oxybutynin chloride in association with alcohol has been reported in a 13-year-old boy who experienced memory loss, and in a 34-year-old woman who developed stupor, followed by disorientation and agitation on awakening, dilated pupils, dry skin, cardiac arrhythmia, and retention of urine. Both patients recovered fully with symptomatic treatment.

Plasma concentrations of oxybutynin begin to decline 24 hours after GELNIQUE application. If overexposure occurs, monitor patients until symptoms resolve.

Keep out of reach of children.

Storage

Store at room temperature, 25°C (77°F). Temporary storage between 15 - 30°C (59 - 86°F) is also permitted. Keep GELNIQUE and all medications in a safe, secure place and out of the reach of children.
