

Biomarker Assays for Lung Ca Making Progress

BY SUSAN LONDON

CORONADO, CALIF. — A variety of lung cancer-associated biomarkers are being tested in assays that may improve diagnosis and treatment of this disease, according to three studies reported at a joint conference of the American Association for Cancer Research and the International Association for the Study of Lung Cancer.

Blood-Based Biomarker Profile

A blood-based biomarker profile discriminates well between patients who have early-stage lung cancer and those individuals who are cancer free but at high risk, reported Dr. Gina Lee, a pulmonary and critical care physician at the University of California, Los Angeles.

She and her colleagues hypothesized that molecular changes in the developing tumor environment would be reflected in changes in levels of inflammatory, angiogenic, and tumorigenic proteins that can be detected in peripheral blood.

They used a bead-based multiplex immunoassay to assess levels of 40 biomarkers in serum samples from 90 patients who had lung cancer of any stage and from 56 cancer-free controls who were at high risk because of lengthy former smoking status and older age.

Levels of 21 biomarkers differed significantly between the 28 patients with stage I lung cancer and the cancer-free controls.

In a logistic regression model that focused on selected biomarkers, participants were more likely to have stage I cancer if they had higher levels of interleukin 2 (odds ratio, 51.4), interleukin 3 (OR, 11.0), and macrophage-derived chemokine (OR, 10.9).

“Our results suggest that we can find tumor-associated biomarkers that are differentially expressed in stage I vs. at-risk controls,” Dr. Lee said. “However, we are also interested in the clinical scenario where individuals present to clinicians with a lung nodule seen on chest x-ray or a CT scan of indeterminate significance.”

Therefore, she and her colleagues will evaluate the 40 biomarkers in pre- and postresection serum samples from patients in the ACOSOG (American College of Surgeons Oncology Group) Z4031 trial. Roughly one-fifth of patients undergoing resection for lung nodules in that trial were found to have benign lung disease.

High-Throughput Protein Assay

A protein signature identified by a high-throughput assay correctly classifies the large majority of patients with and without lung cancer, reported Dr. Rachel Ostroff, clinical research director at SomaLogic Inc., a diagnostic development company in Boulder, Colo.

The SOMAmer technology used in the study relies on aptamers (oligonucleotides that bind to specific proteins with high affinity) to measure 825 proteins in serum simultaneously with

subpicomolar sensitivity, she explained.

The investigators analyzed more than 1,300 serum samples from patients with stage I-III non-small cell lung cancer (20%) and two control groups: individuals with benign calcified pulmonary nodules (40%) and long-term smokers with no evidence of cancer (40%). They were divided into training and verification sets.

Analyses identified a signature of 12 proteins that were differentially ex-

pressed between the groups with and without lung cancer, including cell adhesion molecules, cytokines, angiogenesis markers, and tyrosine kinases, among others.

The signature had an area under the curve of 0.91 in the training set and 0.90 in the verification set, Dr. Ostroff reported. In the training set, sensitivity was 91% for cancer of all stages (90% for stage I) and specificity was 84%. In the

verification set, sensitivity was 89% for cancer of all stages (87% for stage I) and specificity was 84%.

The signature has also been tested in breast, prostate, and other cancers. “Certainly, some of the markers are also differentially expressed in those cancers, as you would expect,” Dr. Ostroff said. “But ... when you combine all of those 12 markers together, it is much more specific for lung cancer than those others.”

NEW FOR HYPERTENSION

TWYNSTA is the only ARB/CCB that contains

TELMISARTAN

the active ingredient in MICARDIS®

Important Safety Information

WARNING: AVOID USE IN PREGNANCY

When used in pregnancy, drugs that act directly on the renin-angiotensin system can cause injury and even death to the developing fetus. When pregnancy is detected, TWYNSTA® (telmisartan/amlo地平ine) tablets and MICARDIS® (telmisartan) tablets should be discontinued as soon as possible (see *Warnings and Precautions*).

Indication

TWYNSTA is indicated for the treatment of hypertension, alone or with other antihypertensive agents. It may also be used as initial therapy in patients who are likely to need multiple drugs to achieve their blood pressure goals. Base the choice of TWYNSTA tablets as initial therapy for hypertension on an assessment of potential benefits and risks including whether the patient is likely to tolerate the starting dose of TWYNSTA tablets. Consider the patient's baseline blood pressure, the target goal, and the incremental likelihood of achieving goal with a combination compared with monotherapy when deciding whether to use TWYNSTA tablets as initial therapy.

Hypotension

Volume depletion and/or salt depletion should be corrected in patients before initiation of therapy or start treatment under close medical supervision with a reduced dose, otherwise symptomatic hypotension may occur. Observe patients with severe aortic stenosis closely for acute hypotension when administering amlodipine.

Hepatic Impairment

In patients with impaired hepatic function, initiate telmisartan at low doses and titrate slowly, or initiate amlodipine at 2.5 mg. The lowest dose of TWYNSTA is 40/5 mg; therefore, initial therapy with TWYNSTA is not recommended in hepatically impaired patients.

Renal Impairment

Monitor carefully in patients with impaired renal function, especially in patients whose renal function may depend on the activity of the renin-angiotensin-aldosterone system (RAAS) (eg, patients with severe congestive heart failure or renal dysfunction); treatment of these patients with ACE inhibitors and ARBs has been associated with oliguria and/or progressive azotemia and, rarely, with acute renal failure and/or death. In patients with unilateral or bilateral renal artery stenosis, increases in serum creatinine or blood urea nitrogen may occur.

Dual RAAS Blockade

When adding an ACE inhibitor to an ARB, monitor renal function closely. Use of telmisartan with ramipril is not recommended.

Other

Uncommonly, increased frequency, duration, and/or severity of angina or acute myocardial infarction have developed in patients treated with calcium channel blockers, particularly patients with severe obstructive coronary artery disease. Closely monitor patients with heart failure.

Adverse Events

In clinical trials, the most commonly reported adverse events with TWYNSTA that were more frequent than with placebo were peripheral edema (4.8% vs 0%), dizziness (3.0% vs 2.2%), clinically meaningful orthostatic hypotension (6.3% vs 4.3%), and back pain (2.2% vs 0%).

Special Populations

In clinical studies, the magnitude of blood pressure lowering with TWYNSTA in black patients approached that observed in non-black patients, but the number of black patients was limited. TWYNSTA is not recommended as initial therapy in patients who are 75 years or older, or who are hepatically impaired. In nursing mothers, nursing or TWYNSTA should be discontinued.

Tumor MicroRNA Analysis

A trio of tumor microRNAs predict de novo resistance to first-line chemotherapy among patients with small cell lung cancer, reported Dr. Glenn J. Weiss, a pulmonary oncologist with Scottsdale (Ariz.) Healthcare and the Translational Genomics Research Institute (TGen) in Phoenix.

"Small cell lung cancer patients have not had key breakthroughs for improved therapy in years, in part, because a one-size-fits-all approach for treatment is the current standard," he commented in an interview.

In the study, which was funded in part by the TGen Foundation, he and his colleagues extracted RNA from formalin-fixed, paraffin-embedded tumor specimens obtained from 34 patients with small cell lung cancer before they started chemotherapy, which was a platinum-based regimen in most cases.

Study results, reported in a poster, showed that of 21 evaluable patients, 4 (19%) had chemoresistance (defined as progression despite chemotherapy).

MicroRNA array analyses identified 16 microRNA biomarkers as possible predictors of progression.

Polymerase chain reaction analyses validated that three of them—miR-92a-2*, miR-147, and miR-574-5p—were indeed associated with progression, Dr. Weiss said.

The investigators are currently assessing how the identified microRNAs may reduce a tumor's sensitivity to chemotherapy, according to Dr. Weiss.

"If we can independently validate our findings in other tumor sample sets collected from small cell lung cancer patients, we can begin to explore [by] using these microRNAs to design better clinical trials and perhaps find new therapies

that help patients at higher risk for resistance to current standard chemotherapy treatment," he concluded. ■

Disclosures: Dr. Lee reported that she had no conflicts of interest related to the study. Dr. Ostroff's employer is the manufacturer of the study assay. Dr. Weiss has filed patents for the use of microRNAs as theranostics, and has received funding from the Sylvia-Chase Foundation, the American Cancer Society, the IBIS Foundation of Arizona, the TGen Foundation, and Scottsdale Healthcare to conduct this work.

AN AMLODIPINE

a long-acting CCB

TEAM UP WITH TWYNSTA—HELP HYPERTENSIVE PATIENTS ACHIEVE SIGNIFICANT BP REDUCTIONS^{1,2}

All 4 dosage strengths of TWYNSTA® (telmisartan/amlodipine) tablets demonstrated significant reductions in cuff DBP and SBP compared to respective individual monotherapies.¹

Study Design: A randomized, double-blind, 8-week, 4 x 4 factorial design trial of Stage-1 and Stage-2 hypertensive patients* (baseline BP: 153.2/101.7 mmHg) evaluated TWYNSTA vs telmisartan and amlodipine alone (N=1461). The primary endpoint was change in the in-clinic seated trough DBP. SBP/DBP reductions were as follows: -21.0/-16.0 mmHg, TWYNSTA 40/5 mg; -23.8/-19.6 mmHg, TWYNSTA 40/10 mg; -21.6/-17.8 mmHg, TWYNSTA 80/5 mg; -25.8/-19.6 mmHg, TWYNSTA 80/10 mg. Reduction with placebo was -1.6/-5.9 mmHg.^{2†}

*According to the JNC 7, Stage-1 hypertension is defined as 140-159 mmHg SBP or 90-99 mmHg DBP. Stage-2 hypertension is \geq 160 mmHg SBP or \geq 100 mmHg DBP.³

†Standard deviation was 11.9/7.6 mmHg, TWYNSTA 40/5 mg; 13.2/7.9 mmHg, TWYNSTA 40/10 mg; 12.7/8.5 mmHg, TWYNSTA 80/5 mg; 14.2/7.9 mmHg, TWYNSTA 80/10 mg; 16.7/9.4 mmHg, placebo.²

ARB: Angiotensin receptor blocker. CCB: Calcium channel blocker. DBP: Diastolic blood pressure. SBP: Systolic blood pressure. JNC 7: The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure.
