# Elderly Benefit From Aggressive Statin Therapy

BY DEBRA L. BECK Contributing Writer

TORONTO — Elderly patients at high risk for acute cardiovascular events benefit as much from LDL cholesterol reduction as do younger patients but are significantly less likely to be prescribed statins, according to study findings presented at the annual meeting of the Society of General Internal Medicine.

"Just as in younger patients, the mag-

control of hyperglycemia.

PRECAUTIONS

INDICATIONS AND USAGE

Rx ONLY BRIEF SUMMARY. Please see package insert for

insulin detemir (rDNA origin) injection

CONTRAINDICATIONS LEVENIR is contraindicated in patients hypersensitive to insulin detemir or one of its excipients.

WARNINGS Hypoglycemia is the most common adverse effect of insulin therapy, including LEVEMIR. As with all insulins the timing of hypoglycemia may differ among various insulin formulations.

Glucose monitoring is recommended for all patients with diabetes.

LEVEMIR is not to be used in insulin infusion pumps

Any change of insulin dose should be made cautiously and only under medical supervision. Changes in insulin strength, timing of dosing, manufacturer, type (e.g., regular, NPH, or insulin analogs), species (animal, human), or method of manufacture (rDNA versus animal-source insulin) may result in the need for a change in dosage. Concomitant oral antidiabetic treatment may need to be adjusted.

General Inadequate dosing or discontinuation of treatment may lead to hyperglycemia and, in patients with type 1 diabetes, diabetic ketoacidosis. The first symptoms of hyperglycemia usually occur gradually over a period of hours or days. They include nausea, vomiting, drowsiness, flushed dry skin, dry mouth, increased urination, thirst and loss of appetite as well as acetone breath. Untreated hyperglycemic events are potentially fatal.

LEVEMIR is not intended for intravenous or intramuscular administration. The prolonged duration of activity of insulin

detemir is dependent on injection into subcutaneous tissue Intravenous administration of the usual subcutaneous dose could result in severe hypoglycemia. Absorption after intramuscular administration is both faster and more exten than absorption after subcutaneous administration.

LEVEMIR should not be diluted or mixed with any other insulin preparations (see PRECAUTIONS, Mixing of Insulins).

Insulin may cause sodium retention and edema, particularly if previously poor metabolic control is improved by intensified insulin therapy.

Lipodystrophy and hypersensitivity are among potential clinical adverse effects associated with the use of all insulins.

As with all insulin preparations, the time course of LEVEMIR action may vary in different individuals or at different times in the same individual and is dependent on site of injection, blood supply, temperature, and physical activity.

Adjustment of dosage of any insulin may be necessary if patients change their physical activity or their usual meal plan.

Hypoglycemia As with all insulin preparations, hypoglycemic reactions may be associated with the administration of LEVEMIR. Hypoglycemia

nitude of cardiovascular benefit is proportional to the magnitude of LDL reduction," said Dr. Catherine Rahilly, of the Massachusetts Veterans Epidemiology Research and Information Center at Boston University and the Boston Veterans Affairs (VA) Healthcare System.

"The evidence supports treating older patients with the same high doses of statins we use in younger patients," she said.

Although it's well known that a graded relationship between magnitude of LDL reduction and magnitude of cardiovascular benefit exists in general in the cardiovascular population, there has been debate as to whether aggressive LDL cholesterol reduction is similarly beneficial in elderly patients.

Dr. Rahilly and her colleagues studied 23,513 veterans from the New England VA Healthcare database who were diagnosed with coronary artery disease, peripheral vascular disease, or diabetes mellitus. Eligible subjects were followed retrospec-

weeks. On rare occasions, injection site reactions may require discontinuation of LEVEMIR. In some instances, these reactions may be related to factors other than insulin, such as irritants in a skin cleansing agen

poor injection technique.

Systemic allergy: Generalized allergy to insulin, which is less common but potentially more serious, may cause rash (including pruritus) over the whole body, shortness of breath, wheezing, reduction in blood pressure, rapid pulse, or sweating. Severe cases of generalized allergy, including anaphylactic reaction, may be life-threatening.

Intercurrent Conditions Insulin requirements may be altered during intercurrent conditions such as illness, emotional disturbances, or other stresses.

# INDICATIONS AND USAGE LEVEMIR is indicated for once- or twice-daily subcutaneous administration for the treatment of adult and pediatric patients with type 1 diabetes mellitus or adult patients with type 2 diabetes mellitus who require basal (long acting) insulin for the control of burger/usemia Information for Patients

Information for Patients LEVEMIR must only be used if the solution appears clear and colorless with no visible particles, Patients should be informed about potential risks and advantages of LEVEMIR therapy, including the possible side effects. Patients should be offered continued education and advice on insulin therapies, injection technique, life-style management, regular glucose monitoring, periodic glycosylated hemoglobin testing, recognition and management of hypo- and hyperglycemia, adherence to meal planning, complications of insulin therapy, timing of dosage, instruction for use of injection devices and proper storage of insulin. Patients should be informed that frequent, patient-performed blood glucose measurements are needed to achieve effective glycemic control to avoid both hyperglycemia and hypoglycemia. Patients must be instructed on handling of special situations such as intercurrent conditions (illness, stress, or emotional disturbances), an inadequate or skipped insulin or emotional disturbances), an inadequate or skipped insulin dose, inadvertent administration of an increased insulin dose, inadequate food intake, or skipped meals. Refer patients to the LEVEMIR "Patient Information" circular for additional informati

As with all patients who have diabetes, the ability to concentrate and/or react may be impaired as a result of hypoglycemia or hyperglycemia Patients with diabetes should be advised to inform their health care professional if they are pregnant or are contemplating pregnancy (see PRECAUTIONS, Pregnancy).

**Laboratory Tests** As with all insulin therapy, the therapeutic response to LEVEMIR should be monitored by periodic blood glucose tests. Periodic measurement of HbA<sub>1c</sub> is recommended for the monitoring of long-term glycemic control.

ous tissue.

Drug Interactions A number of substances affect glucose metabolism and may require insulin dose adjustment and particularly close monitoring. The following are examples of substances that may reduce the blood-glucose-lowering effect of insulin: corticosteroids, danazol, diuretics, sympathomimetic agents (e.g., epinephrine, albuterol, terbutaline), isoniazid, phenothiazine derivatives, somatropin, thyroid hormones, estrogens, progestogens (e.g., in oral contraceptives).

(e.g., in oral contraceptives). The following are examples of substances that may increase the blood-glucose-lowering effect of insulin and susceptibility to hypoglycemia: oral antidiabetic drugs, ACE inhibitors, disopyramide, fibrates, fluoxetine, MAO inhibitors, propoxyphe salicylates, somatostatin analog (e.g., octreotide), and the antibility of the salicylation of the salicylates sulfonamide antibiotics.

Suironamide antibiotics. Beta-blockers, clonidine, lithium salts, and alcohol may either potentiate or weaken the blood-glucose-lowering effect of insulin. Pentamidine may cause hypoglycemia, which may sometimes be followed by hyperglycemia. In addition, under the influence of sympatholytic medicinal products such as beta-blockers, clonidine, guanethidine, and reserpine, the signs of hypoglycemia may be reduced or absent.

The results of *in-vitro* and *in-vivo* protein binding studies demonstrate that there is no clinically relevant interaction betweer insulin detemir and fatty acids or other protein bound drugs.

## Mixing of Insulins If LEVEMIR is mixed with other insulin preparations, the profile

A constraint of one or both individual components may change. Mixing LEVEMIR with insulin aspart, a rapid acting insulin analog, resulted in about 40% reduction in AUC<sub>(0-20)</sub> and C<sub>max</sub> for insulin aspart compared to separate injections when the ratio of insulin aspart to LEVEMIR was less than 50%.

LEVEMIR should NOT be mixed or diluted with any other insulin preparations.

Insulin preparations. Carcinogenicity, Mutagenicity, Impairment of Fertility Standard 2-year carcinogenicity studies in animals have not been performed. Insulin detemir tested negative for genotoxic potential in the *in-vitro* reverse mutation study in bacteria, human peripheral blood lymphocyte chromosome aberration test, and the *in-vivo* mouse micronucleus test.

r-regnancy: Teratogenic Effects: Pregnancy Category C In a fertility and embryonic development study, insulin detemir was administered to female rats before mating, during mating, and throughout pregnancy at doses up to 300 nmol/kg/day (3 times the recommended human dose, based on plasma Area Under the Curve (AUC) ratio). Doses of 150 and 300 nmol/kg/day produced numbers of litters with visceral anomalies. Doses up to 900 nmol/kg/day (approximately) 135 times the recommended human dose based on AUC ratio) were given to rabbits during organogenesis. Drug-dose related increases in the incidence of fetuses with gall bladder abnormalities such as small, bilobed, bifurcated and missing gall bladders were observed at a dose of 900 nmol/kg/day. The rat and rabbit embryofetal development studies that included concurrent human insulin control groups Pregnancy: Teratogenic Effects: Pregnancy Category C In a fertility and empryonic development study insulin deter

indicated that insulin detemir and human insulin had similar effects regarding embryotoxicity and teratogenicity.

# Nursing mothers It is unknown whether LEVEMIR is excreted in significant amounts in human milk. For this reason, caution should be exercised when LEVEMIR is administered to a nursing mother. Patients with diabetes who are lactating may require adjustments in insulin dose, meal plan, or both.

Pediatric use In a controlled clinical study, HbA<sub>1c</sub> concentrations and rates of hypoglycemia were similar among patients treated with LEVEMIR and patients treated with NPH human insulin.

Geriatric use Of the total number of subjects in intermediate and long-term clinical studies of LEVENIR, 85 (type 1 studies) and 363 (type 2 studies) were 65 years and older. No overall differences in safety or effectiveness were observed between these subjects safety or effectiveness were observed between these subjects and younger subjects, and other reported clinical experience has not identified differences in responses between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out. In elderly patients with diabetes, the initial dosing, dose increments, and maintenann dosage should be conservative to avoid hypoglycemic reactio Hypoglycemia may be difficult to recognize in the elderly. ADVERSE REACTIONS

Adverse events commonly associated with human insulin therapy include the following:

Body as Whole: allergic reactions (see PRECAUTIONS, Allergy). Skin and Appendages: lipodystrophy, pruritus, rash. Mild injection site reactions occurred more frequently with LEVEMIR than with NPH human insulin and usually resolved in a few days to a few weeks (see PRECAUTIONS, Allergy). Other:

### Hypoglycemia: (see WARNINGS and PRECAUTIONS).

In trials of up to 6 months duration in patients with type 1 and type 2 diabetes, the incidence of severe hypoglycemia with LEVEMIR was comparable to the incidence with NPH, and, as expected, greater overall in patients with type 1 diabetes (Table 4).

Weight gain: In trials of up to 6 months duration in patients with type 1 and type 2 diabetes, LEVEMIR was associated with somewhat less weight gain than NPH (Table 4). Whether these observed differences represent true differences in the effects of LEVEMIR and NPH insulin is not known, since these trials were not blinded and the protocols (e.g., diet and exercise instructions and monitoring) were not specifically directed at exploring hypotheses related to weight effects of the treatments compared. The clinical significance of the observed differences has not been established. Table 4:

### Table 4: Safety Information on Clinical Studies

			<u>Weig</u>	i <u>ht (kg</u> )	Hypoglycemia (events/subject/month)	
	Treatment	# of subjects	Baseline	End of treatment	Major*	Minor**

	NPH	N=200	79.6	80.9	0.006	0.235

Major = requires assistance of another individual because of neurologic impairment
\*\* Minor = plasma glucose <56 mg/dl, subject able to deal with the
episode him/herself</pre>

### OVERDOSAGE

OVERDOSAGE Hypoglycemia may occur as a result of an excess of insulin relative to food intake, energy expenditure, or both. Mild episodes of hypoglycemia usually can be treated with oral glucose. Adjustments in drug dosage, meal patterns, or exercis may be needed. More severe episodes with coma, seizure, or neurologic impairment may be treated with intramuscular/ subcutaneous glucagon or concentrated intravenous glucose. After apparent clinical recovery from hypoglycemia, continued observation and additional carbohydrate intake may be necessary to avoid reoccurrence of hypoglycemia. More detailed information is available on request.

tively for a combined outcome of first acute myocardial infarction or revascularization.

In their study, significantly fewer elderly patients (older than 75.3 years) were prescribed statins, compared with younger patients (70% vs. 78%-82%; P less than .0001).

Dr. Rahilly said that despite this, there were enough subjects in the oldest age quartile who achieved a large LDL reduction to demonstrate that such patients experienced fewer events than did their counterparts, who had achieved only small or medium LDL reductions.

Preoutcome LDL reduction was categorized as no reduction (less than 10 mg/dL), small reduction (10-40 mg/dL), moderate reduction (40-70 mg/dL), and large reduction (more than 70 mg/dL).

For each age quartile, a significant relationship was seen at any final LDL cholesterol level between the amount of LDL change and the magnitude of risk reduc-

Just as in younger patients, the magnitude of cardiovascular benefit is proportional to the magnitude of LDL reduction. The evidence suggests that older patients may benefit from high statin doses.

tion for the combined outcome of first acute myocardial infarction and surgical or percutaneous revascularization.

patients In who achieved large LDL reductions, compared with those with no reduction, the hazard ratios for the primary outcomes were similar across age quartiles af-

ter adjustment for age, gender, cholesterol-modifying therapy, hypertension, renal disease, thyroid disease, and cerebrovascular disease.

In the subgroup of 2,038 patients aged 80 or older, the hazard ratio for those who achieved only a small reduction in LDL cholesterol was 0.65, dropping to 0.27 for those with the largest LDL reduction, said Dr. Rahilly, also of Brigham and Women's Hospital, Boston.

Median baseline age in the cohort was 67.1 years, and average follow-up time was 3.86 years. In all, 6,150 patients had a myocardial infarction or underwent revascularization during the study.

In her presentation, Dr. Rahilly conceded that the study might have missed outcome events that occurred outside the VA medical system.

They also did not have data on race, smoking, or socioeconomic status and, thus, were unable to control for those variables.

The findings, however, are similar to those seen in previous meta-analyses and in the recently published Study Assessing Goals in the Elderly (SAGE) study, in which a 67% reduction in risk for all-cause death was seen in subjects treated with a daily 80-mg dose of atorvastatin (Circulation 2007;115:700-7). 

associated with the administration of LEVEMIR. Hypoglycemia is the most common adverse effect of insulins. Early warning symptoms of hypoglycemia may be different or less pronounced under certain conditions, such as long duration of diabetes, diabetic nerve disease, use of medications such as beta-blockers, or intensified diabetes control (see PRECAUTIONS, Drug Interactions). Such situations may result in severe hypoglycemia (and, possibly, loss of consciousness) prior to patients' awareness of hypoglycemia. The time of occurrence of hypoglycemia depends on the action profile of the insulins used and may, therefore, change when the treatment regimen or timing of dosing is changed. In patients being switched from other intermediate or long-acting insulin preparations to once- or twice-daily LEVEMIR, dosages can be prescribed on a unit-to-unit basis; however, as with all insulin preparations, dose and timing of administration may need to be adjusted to reduce the risk of hypoglycemia.

Renal Impairment As with other insulins, the requirements for LEVEMIR may need to be adjusted in patients with renal impairment.

# Hepatic Impairment As with other insulins, the requirements for LEVEMIR may need to be adjusted in patients with hepatic impairment.

Injection Site and Allergic Reactions As with any insulin therapy, lipodystrophy may occur at the injection site and delay insulin absorption. Other injection site reactions with insulin therapy may include redness, pain, itching, hives, swelling, and inflammation. Continuous rotation of the injection site within a given area may help to reduce or prevent these reactions. Reactions usually resolve in a few days to a few
